

Background

Action sequences are performed with striking fluency:

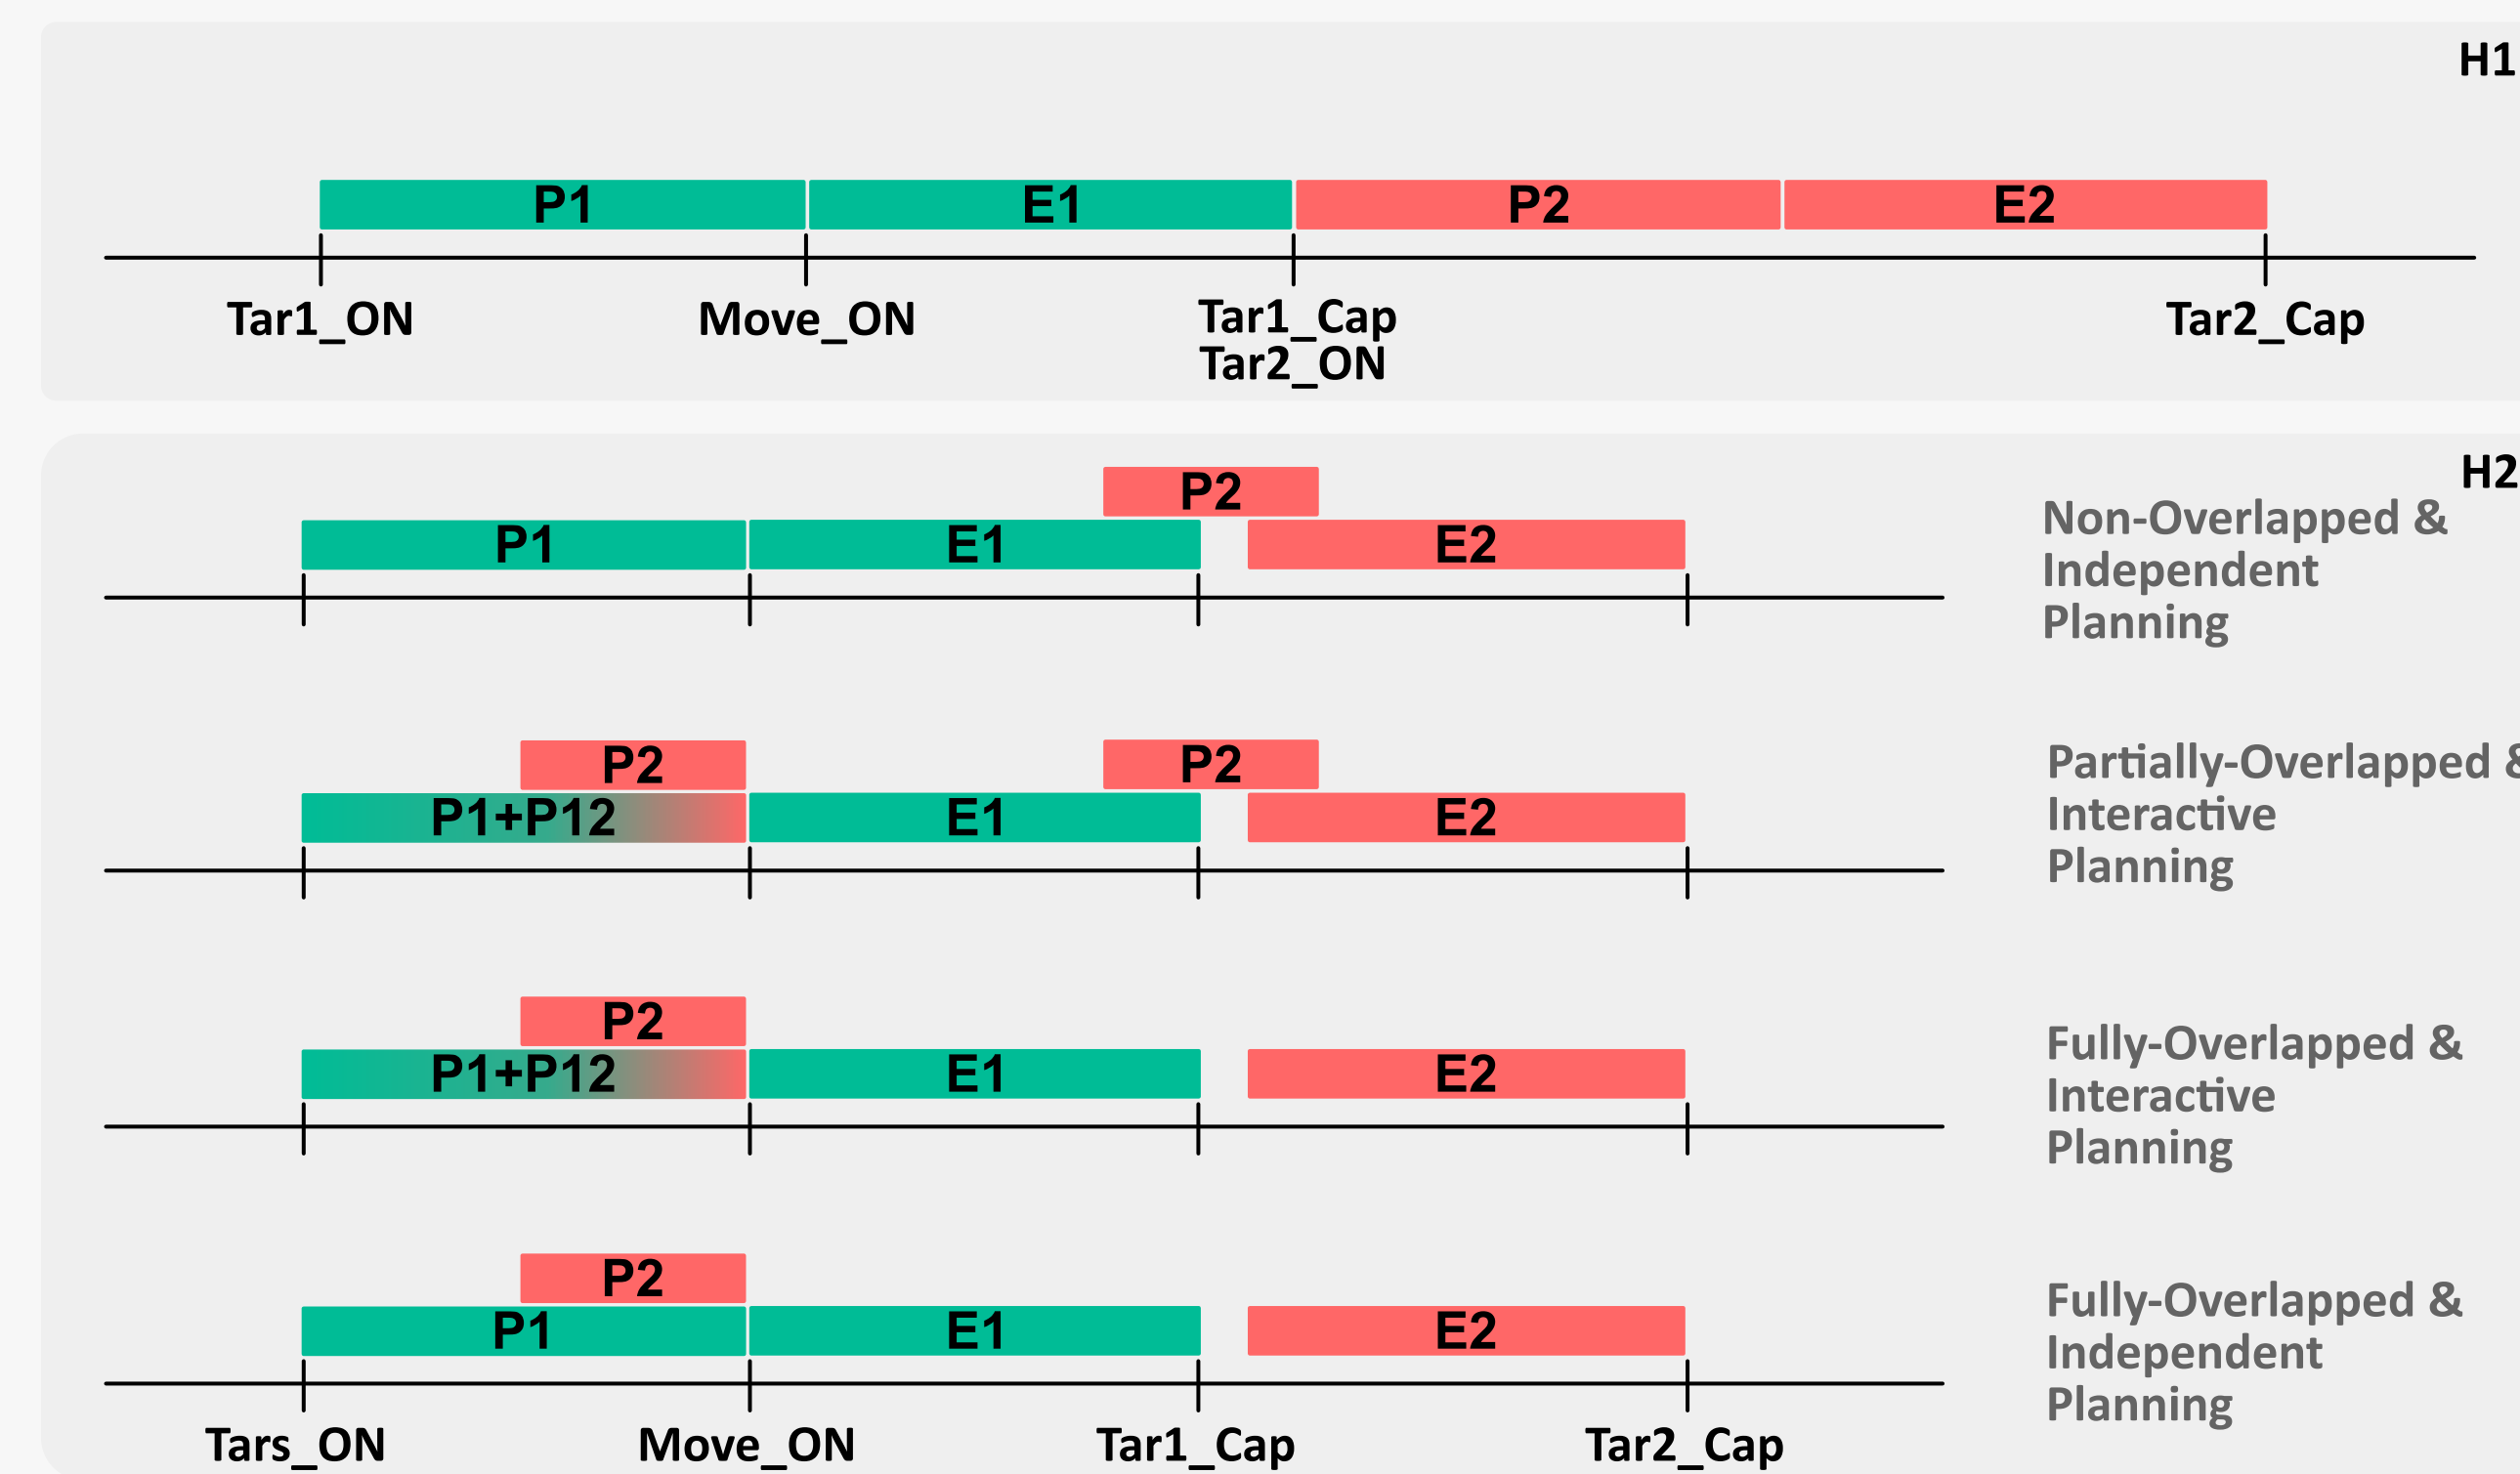

Here, we investigate how the **cortical motor regions** supports the preparation and execution of coarticulated reaching sequences.

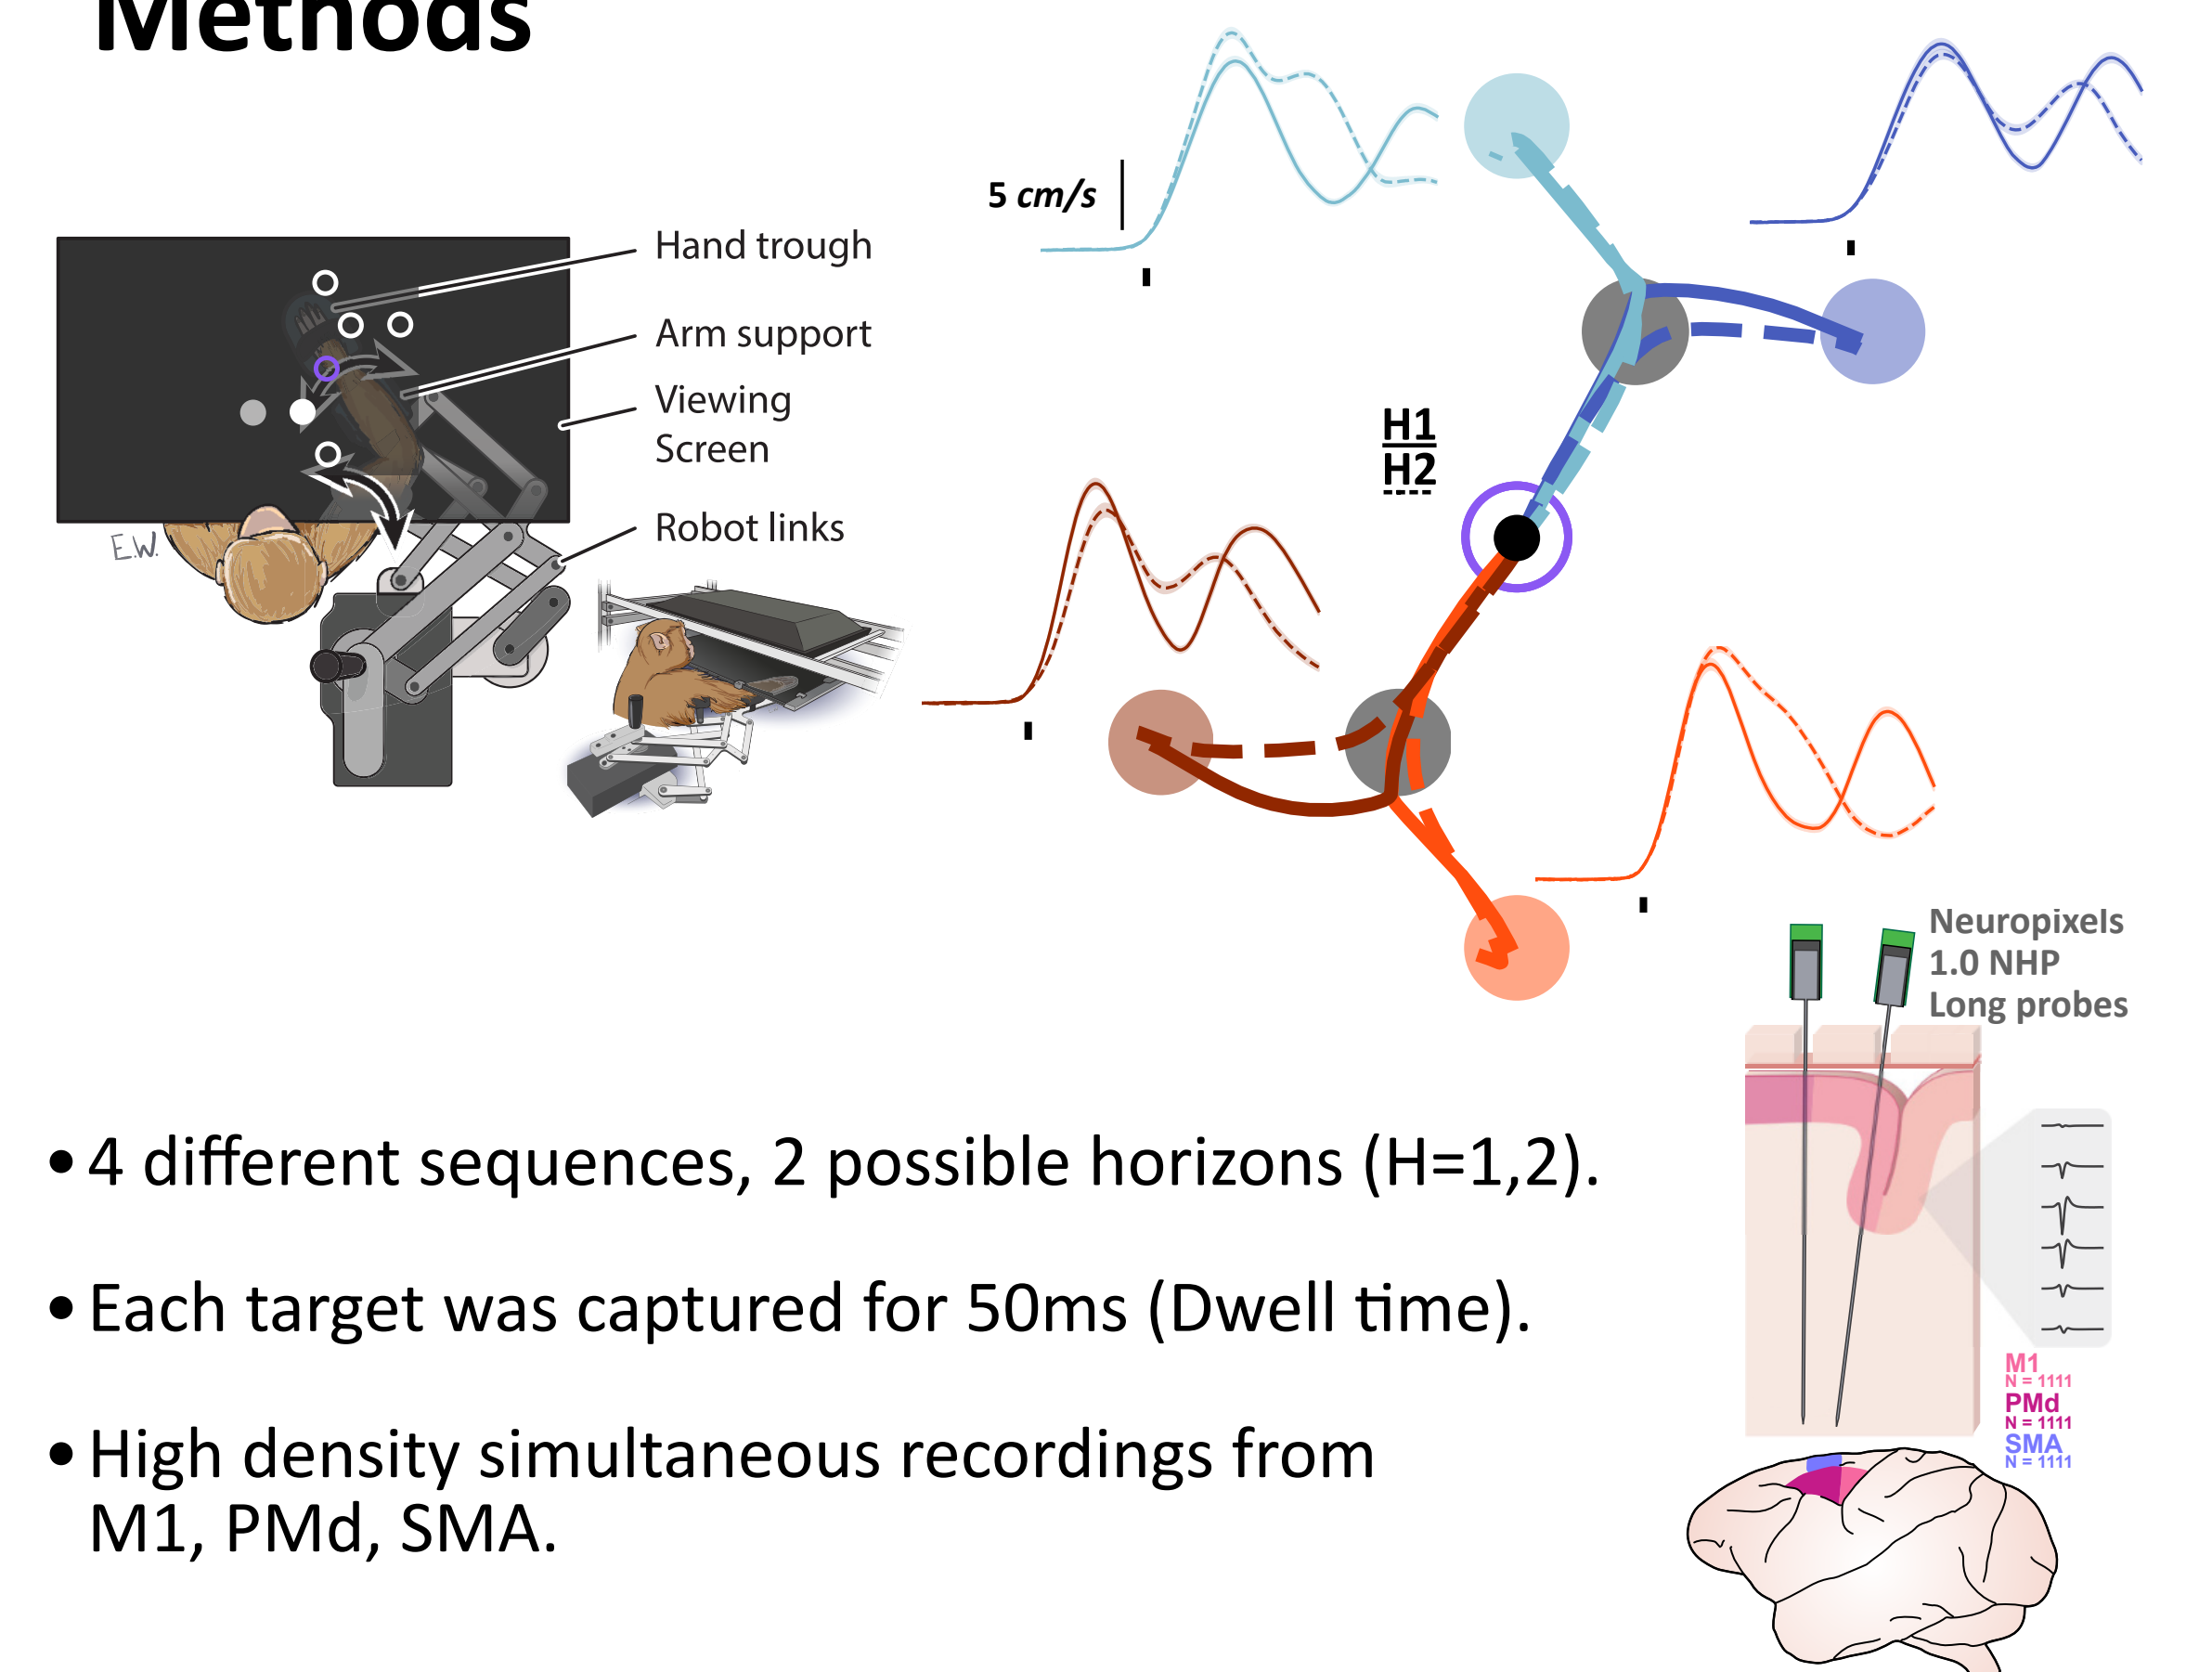

We specifically ask:

Whether the planning of the two reaches **temporally overlap**, and if so, whether they are **independent or interactive**?

Potential Mechanisms

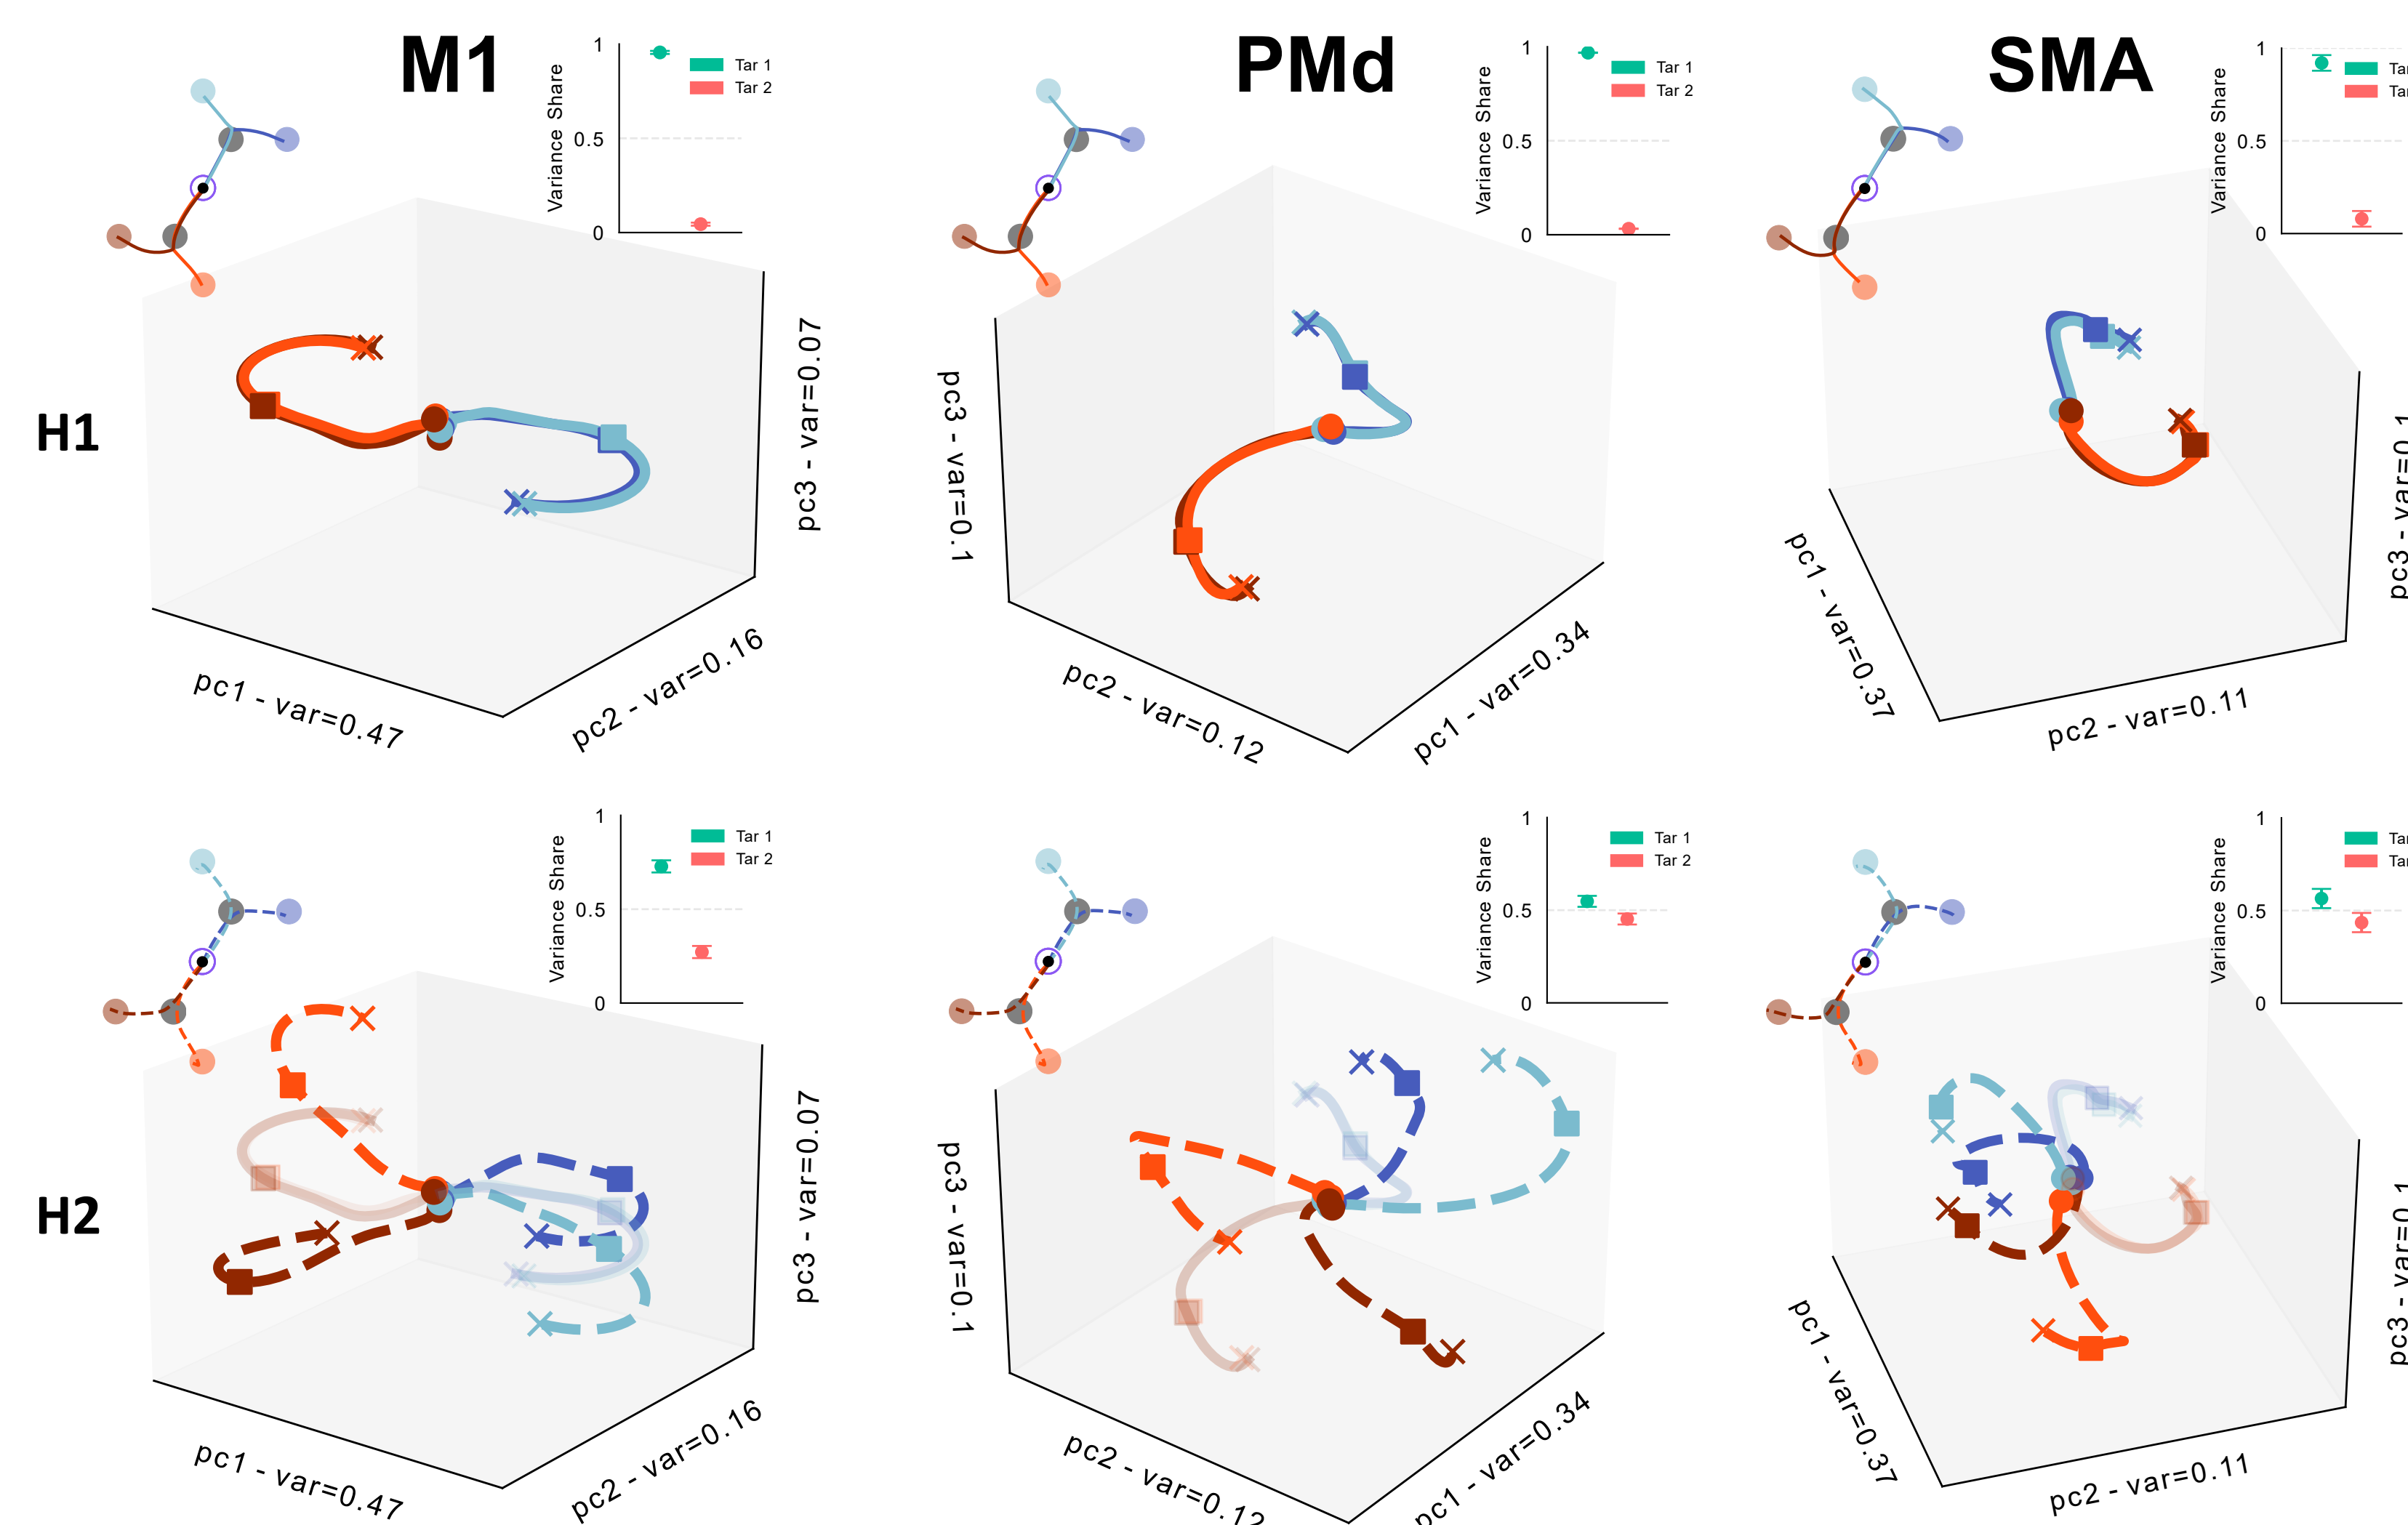

Methods

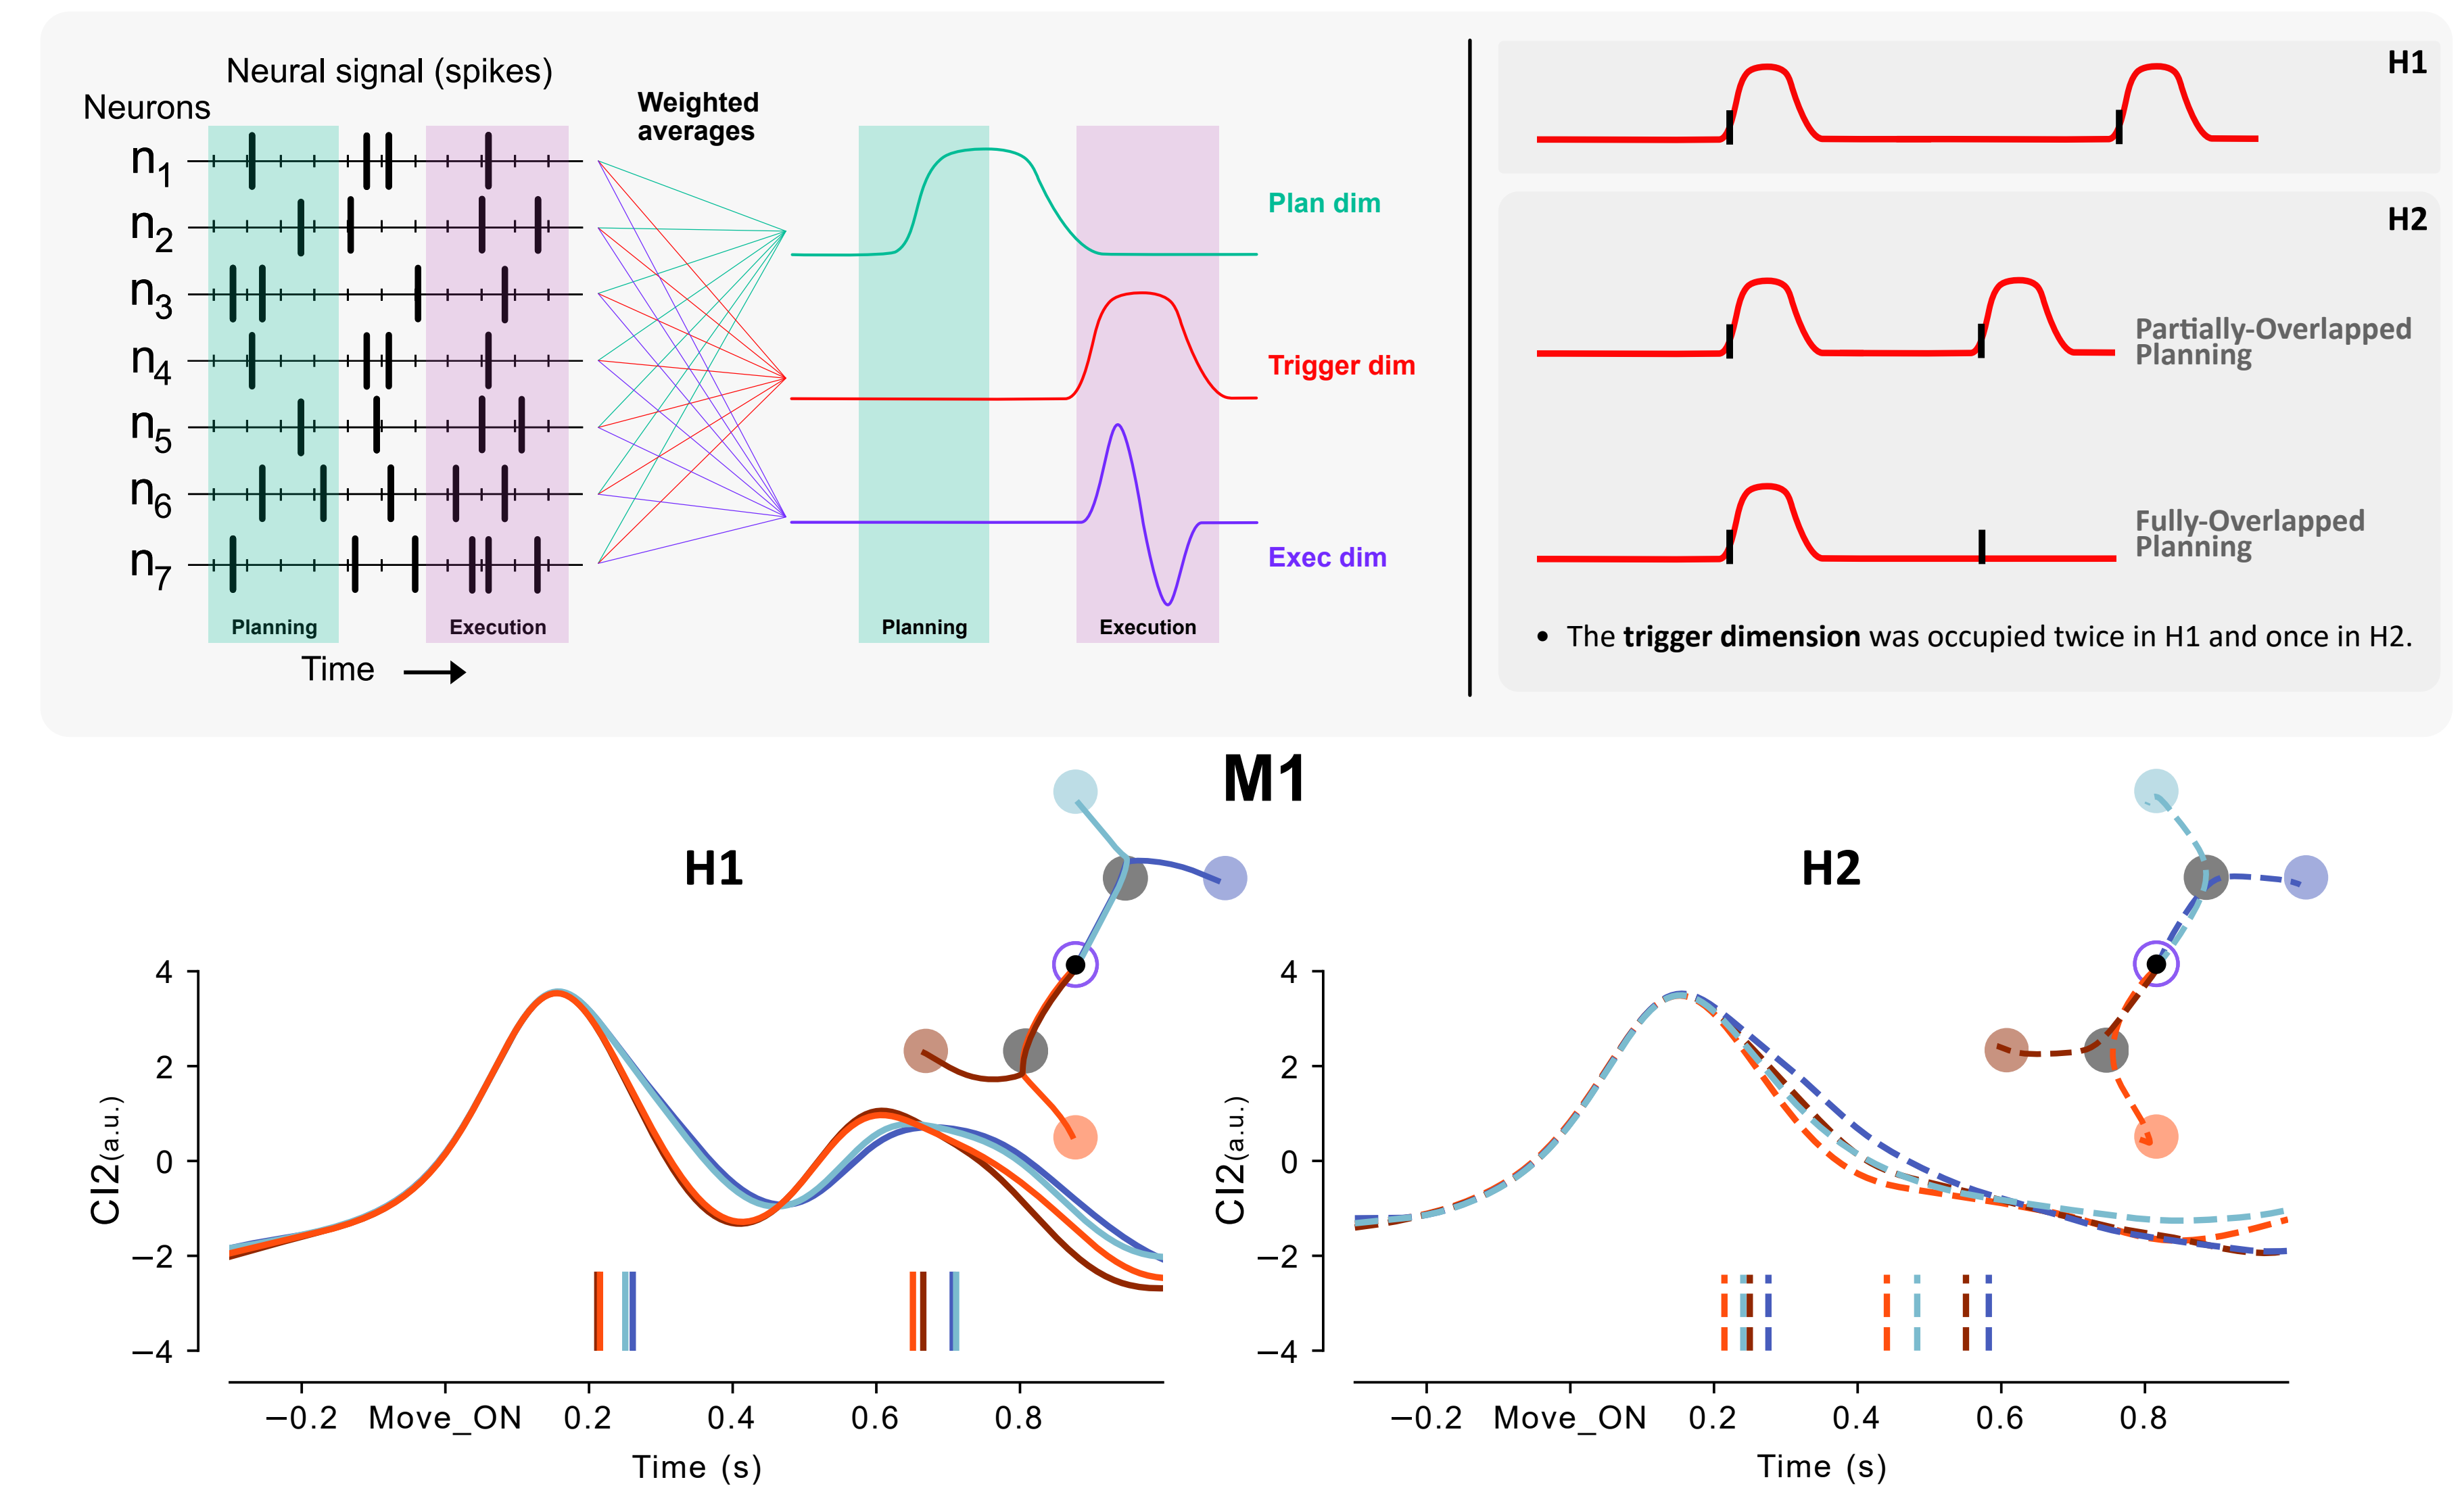

- 4 different sequences, 2 possible horizons (H=1,2).
- Each target was captured for 50ms (Dwell time).
- High density simultaneous recordings from M1, PMd, SMA.

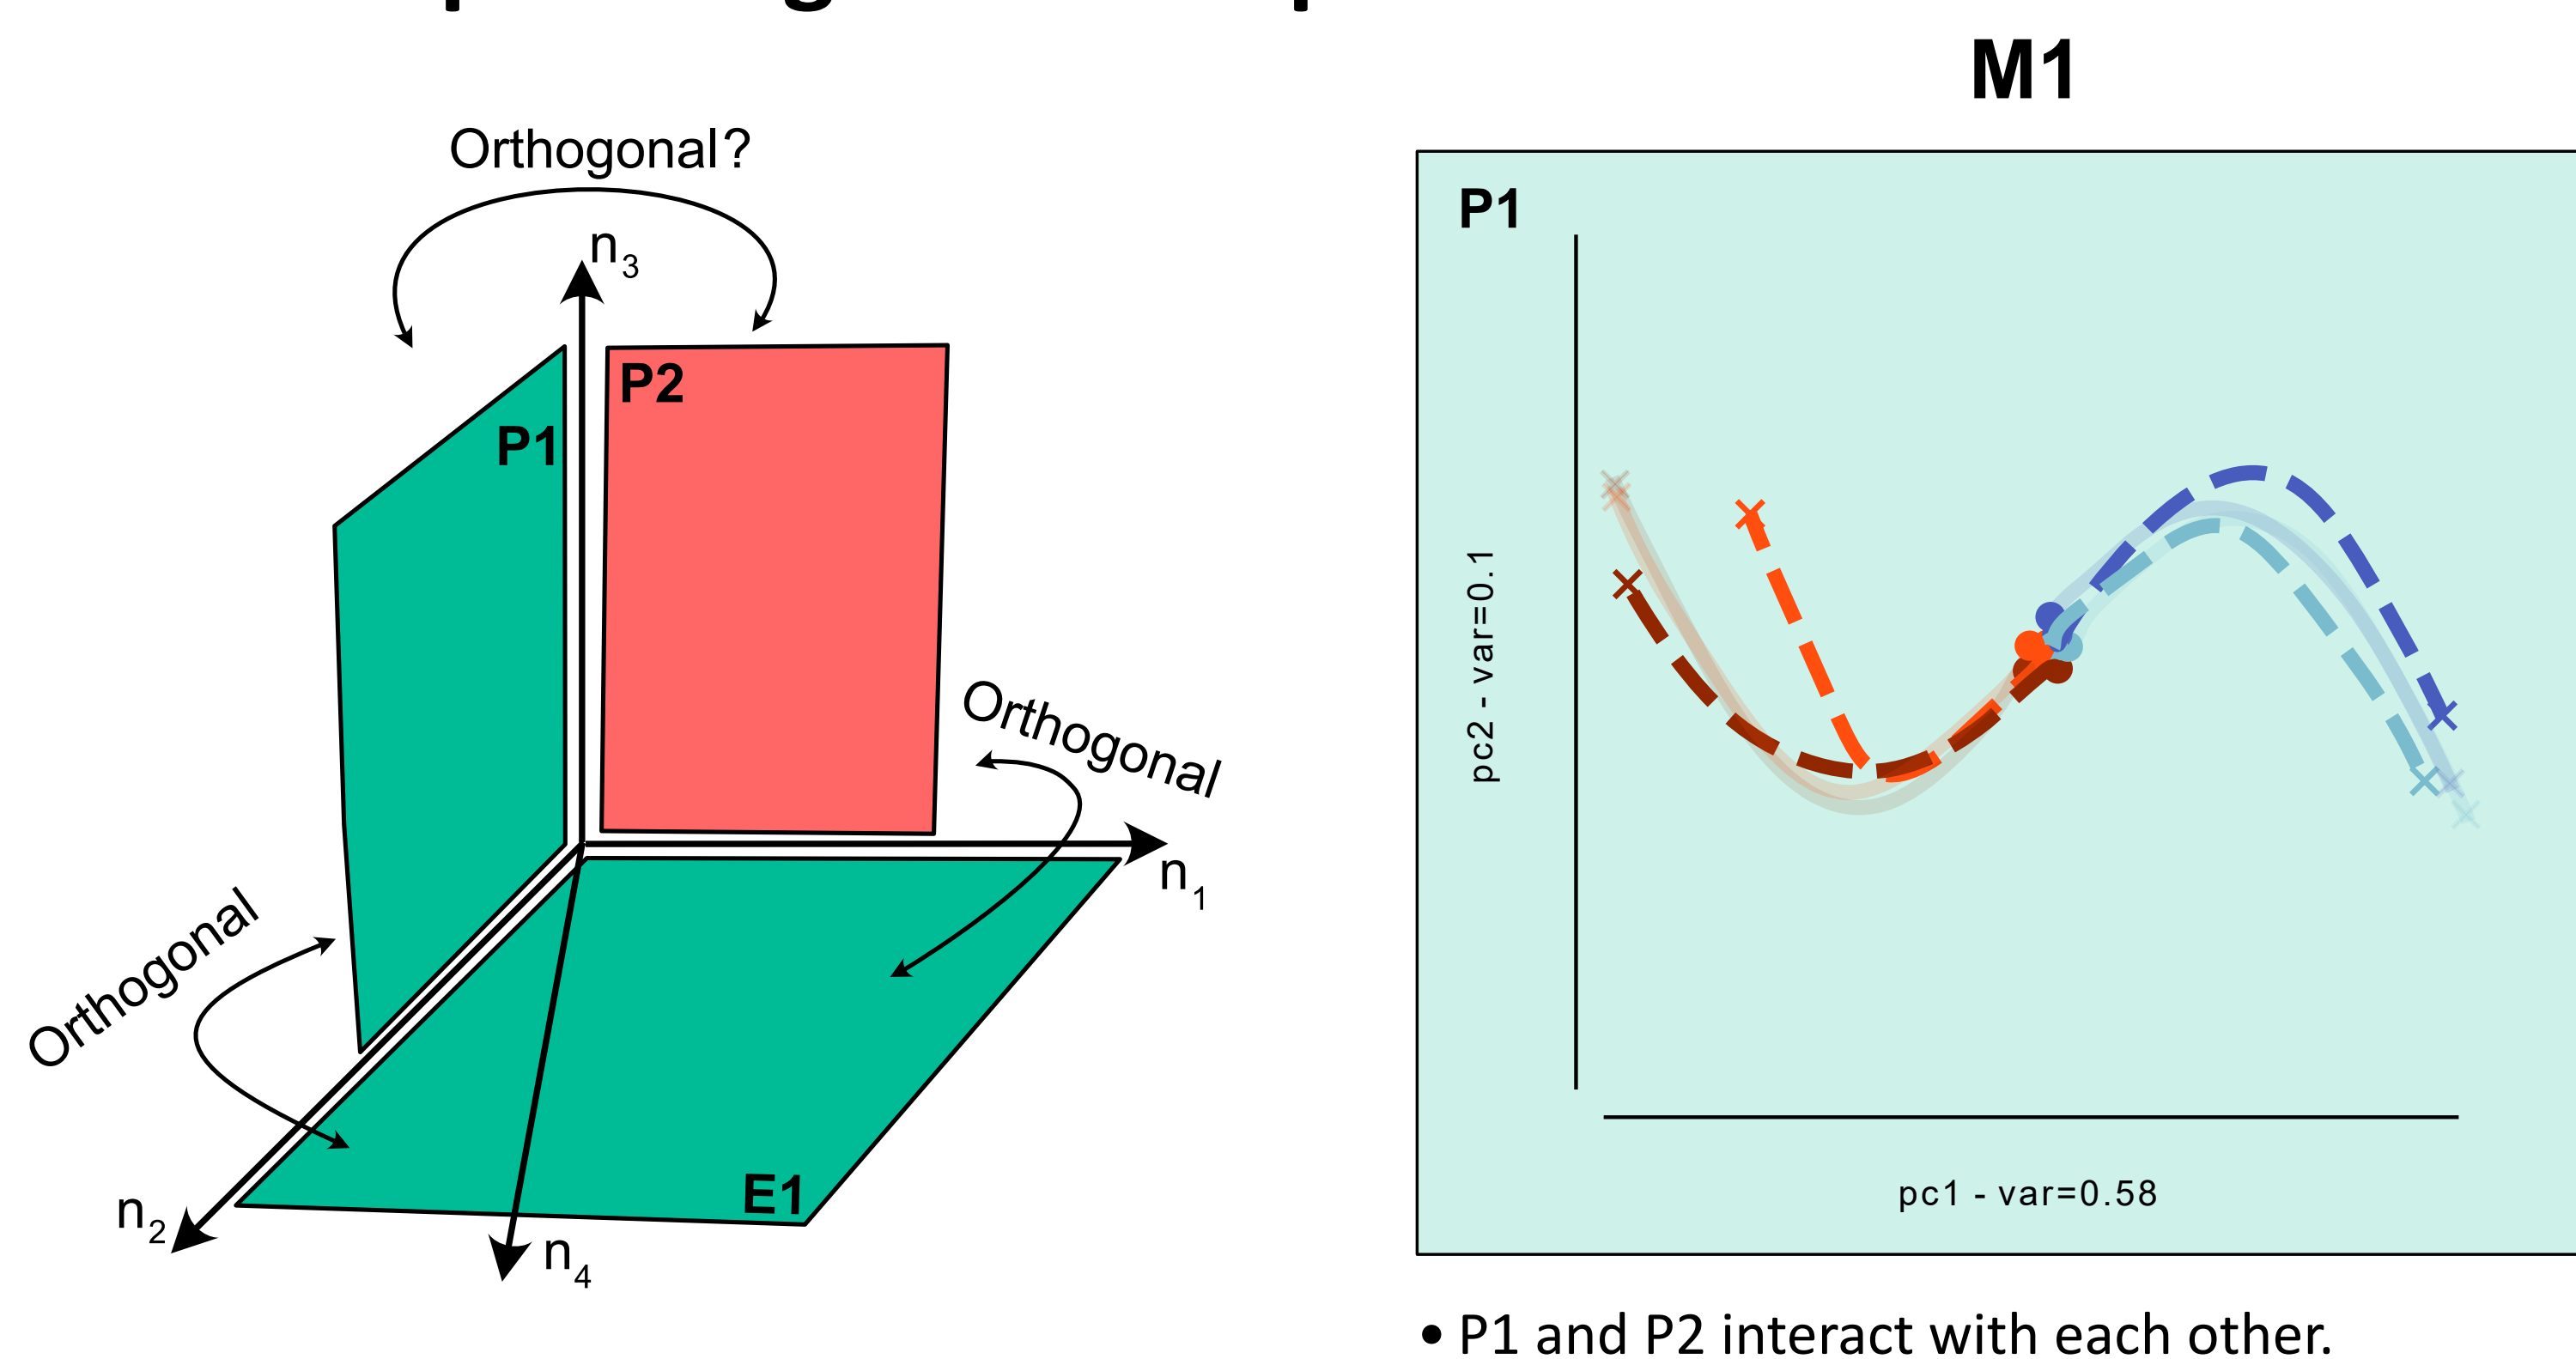

Sequence specific representations pre- and during movement

Fully-Overlapped planning of the sequence

Interactive planning of the sequence

Summary

- The planning of the two reaches in the sequence **fully overlap temporally** before the movement onset.
- The planning of the two reaches are **not fully independent** from each other.

Discussion

- How aligned P1 and P2 are? Are they fully overlapping? or nearly orthogonal? How does this alignment change across areas?
- How differently the sequences are represented across areas?
- What will happen when facing longer sequences?
- How does these areas orchestrate together to produce sequences?
